1. Introduction

Jericho Wind, Inc., a wholly owned subsidiary of NextEra Energy Canada, ULC, (NextEra) is proposing to construct a wind energy project in the Municipality of Lambton Shores and the Township of Warwick, in Lambton County, Ontario and in the Municipality of North Middlesex, in Middlesex County, Ontario. The Project is referred to as the Jericho Wind Energy Centre (the “Project”). All turbines will be located on private lands.

This report has been prepared in accordance with the Ontario Ministry of the Environment (MOE) guideline “Noise Guidelines for Wind Farms – Interpretation for Applying MOE NPC Publications to Wind Power Generation Facilities” (October 2008). This report will form part of the Renewable Energy Approval (REA) application for the Project as required under Ontario Regulation 359/09.

2. Project Layout

Approval is being sought for 99 wind turbine locations, with each turbine rated at 1.6 Megawatts maximum generation capacity. However, only 92 of the wind turbines will ultimately be constructed in order to achieve the Project nameplate generation target of up to 150 Megawatts. All of the wind turbines will feed into a centrally located transformer substation.

The proposed Project is located in the Municipality of Lambton Shores and the Township of Warwick, in Lambton County, Ontario and in the Municipality of North Middlesex, in Middlesex County, Ontario. The Project Study Area consists of the areas being studied for the wind energy component (Wind Energy Centre Study Area), as well as for the interconnection route (i.e., the area being studied for transmission lines to connect the Project to the electrical grid) (Transmission Line Study Area). The Wind Energy Centre Study Area is generally bounded by Lakeshore Road/Bog Line to the north, Egremont Road to the south, the Lambton Shores/North Middlesex municipal boundary to the east and Rawlings Road/Elarton Road to the west, in Lambton County. The Transmission Line Study Area is generally bounded by Kennedy Line, Parkhill Drive and Elginfield Road to the north, Jura Line, Elm Tree Drive and Poplar Hill Road to the south, Fernhill Drive to the east, and the Jericho Road to the west, in Lambton and Middlesex Counties.

The location of the Project Study Area was defined early in the planning process for the proposed wind energy facility, based on the availability of wind resources, approximate area required for the proposed project, and availability of existing infrastructure for connection to the electrical grid. The Project Study Area was used to facilitate information collection.

A figure showing the project location, wind turbine layout and transformer location is attached as Appendix A. The Noise Impact Assessment Report for the Parkhill Interconnect Project is attached as Appendix B.

3. Noise Assessment Guideline

Part V.0.1 of the Ontario Environmental Protection Act R.S.O. 1990 (EPA) addresses the approvals process required for renewable energy projects and Ontario Regulation 359/09 outlines the specific requirements for obtaining a Renewable Energy Approval (REA) from the MOE.

As required by O.Reg. 359/09, noise from wind farm projects requiring approval within Ontario are assessed using the MOE guideline: "Noise Guidelines for Wind Farms – Interpretation for Applying MOE NPC Publications to Wind Power Generation Facilities" (PIBS 4709e, October 2008). This guideline sets the definitions, assessment procedures and noise level limits for noise assessments of wind farm projects.

The project area is best defined as Class 3 rural, as per MOE Publication 4709e. A Class 3 Area is defined as "a rural area with an acoustical environment that is dominated by natural sounds having little or no road traffic, such as the following: a small community with less than 1000 population; agricultural area; a rural recreational area such as a cottage or a resort area; or a wilderness area." The MOE noise level limits, at integer wind speeds, for points of reception in Class 3 areas are summarized in Table 1 below.

Table 1. Noise Level Limits for Wind Turbines

Point of Reception Classifications	1-hr L _{EQ} Sound Level Limit (dB(A)) at 10m height Wind Speeds (m/s)				
	Less than or equal to 6 m/s	7 m/s	8 m/s	9 m/s	Greater than or equal to 10 m/s
Class 1 & 2 Areas	45.0	45.0	45.0	49.0	51.0
Class 3 Areas	40.0	43.0	45.0	49.0	51.0

4. Noise Sources

Table 6 and Table 7 of Section 9 provide the co-ordinates of all noise sources considered in the noise impact analysis and assessment.

4.1 Wind turbine noise sources

The wind turbine technology proposed for this Project is the GE 1.6-100 Wind Turbine with Low-Noise Trailing Edges (LNTE). This model has the following features:

- 100 metre rotor diameter, with a swept area of 7,854 m²
- Hub height of 80 metres
- Maximum generation capacity of 1.62 Megawatts

The MOE requires that the cumulative noise impact of existing or proposed¹ wind farms also be included in the noise impact analysis. To that end all existing or proposed wind turbines within 5 kilometres of the Project were included in the noise impact analysis. These projects are:

- NextEra Bornish Wind Energy Centre
 - Proposed wind turbine installations
 - Consists of 48 proposed GE 1.6-100 LNTE wind turbines with a rated capacity of 1.6 Megawatts
- Ravenswood Wind Farm
 - Existing wind turbine installations
 - Consists of six Vestas V82 1.65 MW wind turbines
- Suncor Energy Adelaide Wind Power Project
 - Proposed wind turbine installations
 - Consists of 22 Siemens 2.3-113 wind turbine generators, derated to a capacity of 2.221 MW as outlined in the *Adelaide Wind Power Project Noise Assessment Report*
- Suncor Energy Cedar Point Wind Power Project
 - Proposed wind turbine installations
 - Consists of 55 Siemens 2.3-113 wind turbine generators, derated to capacities of 2.221 MW, 2.126 MW and 2.030 MW as outlined in the *Cedar Point Wind Power Project Noise Assessment Report*

Manufacturers' noise data for all assessed wind turbines are summarized in Table 7 of Section 9. The noise datasheets provided have been prepared and reported in accordance with IEC 61400-11 (equivalent to CAN/CSA-C61400-11). Site specific wind shear measurements were undertaken prior to release of the project, using a meteorological tower installed between 2007 and 2014. The results from this tower indicated that the average summer night time wind shear is 0.33.

The spectral data from the manufacturers for Siemens 2.3-113 wind turbine generators indicate that maximum noise levels occur at nearby receptors at hub height wind speeds of 9.5 m/s; which would occur at wind shear levels of 0.2. Spectral data for the GE 1.6-100 LNTE wind turbine generators indicate that maximum noise levels occur at hub height wind speeds of 14 m/s and greater; occurring at wind shear levels of more than 0.41. While it is not realistic that both turbine models would be operating under this condition, noise calculations were conservatively conducted using manufacturer spectral data for these turbine models that result in maximum noise levels for all assessed wind speeds.

¹ Based on MOE guidelines, proposed projects which have not yet published a site plan have not been accounted for in the noise impact analysis.

4.2 Wind turbine transformer noise sources

The electricity generated by the Jericho Wind Energy Centre will be collected at a central transformer substation. The performance specification of the transformer will require that the noise emissions be measured in accordance with ANSI/IEEE C57.12.90 at the highest (MVA) rating with all fans in operation and at the tap position that creates the highest current. The proposed transformer for the Project is a Prolec GE 102/136/170 MVA transformer. A spare transformer with the same specifications will be stored at the substation and will be used in the event that the primary transformer requires servicing.

The performance specification will require that the average sound pressure level measured in accordance with ANSI C57.12.90 shall not exceed 75 dB(A) over the measurement surface (as defined in the ANSI/IEEE standard). An estimate of the noise emissions expected from the transformer is provided in Table 5. Appendix C includes a detailed calculation to support the transformer emission estimate. Note that a 5dB penalty has been added to the transformer emission level in the noise prediction modelling as per the requirements of PIBS 4709e.

The transformer will be installed on a concrete pad surrounded by gravel. In order to include the effect of reduced absorption in the source zone (as defined by ISO 9613-2), the following reductions in ground absorption have been made for this source (compared to the levels given in *Noise Guidelines for Wind Farms – Interpretation for Applying MOE NPC Publications to Wind Power Generation Facilities*):

- Source zone ground absorption G_s , reduced from 1.0 to 0.0
- Receiver zone ground absorption G_r , unchanged at 0.5
- Middle zone ground absorption, G_m , unchanged at 0.8

These changes have been implemented for the three closest non-participating receptors to the transformer.

The transformer will have a 7.0 metre high noise barrier on the north and east sides of the Project transformer substation, and a 4.5 metre high noise barrier on the south side. The noise barrier should have an absorptive surface on the side facing the transformer with a minimum Noise Reduction Coefficient (NRC) of 0.8. The noise barrier should have a minimum surface density of 20 kg/m² or a minimum Sound Transmission Class (STC) of STC32 and should not have any gaps or cracks. The co-ordinates of the transformer, as well as end-points and corners of the noise barrier are provided in Table 2.

Transformers are planned as part of the Suncor Cedar Point Wind Power Project, Suncor Adelaide Wind Power Project and Bornish Wind Energy Centre. However, all of these transformers are located at distances of greater than 5 km from the Jericho Wind Energy Centre.

Table 2. Transformer and associated noise barrier locations

Identifier	Project	Equipment Make & Model	UTM Coordinates (NAD83 Zone 17N)		Remarks
			Easting	Northing	
J_Trans	Jericho	Prolec 102/136/170 MVA Transformer	427098	4777771	—
Noise Barrier	Jericho	—	427092	4777776	Northwest endpoint
Noise Barrier	Jericho	—	427105	4777776	North/east intersection
Noise Barrier	Jericho	—	427105	4777761	South/east intersection
Noise Barrier	Jericho	—	427091	4777762	Southwest endpoint

The layout of the barrier relative to the transformer is shown in Figure 1.

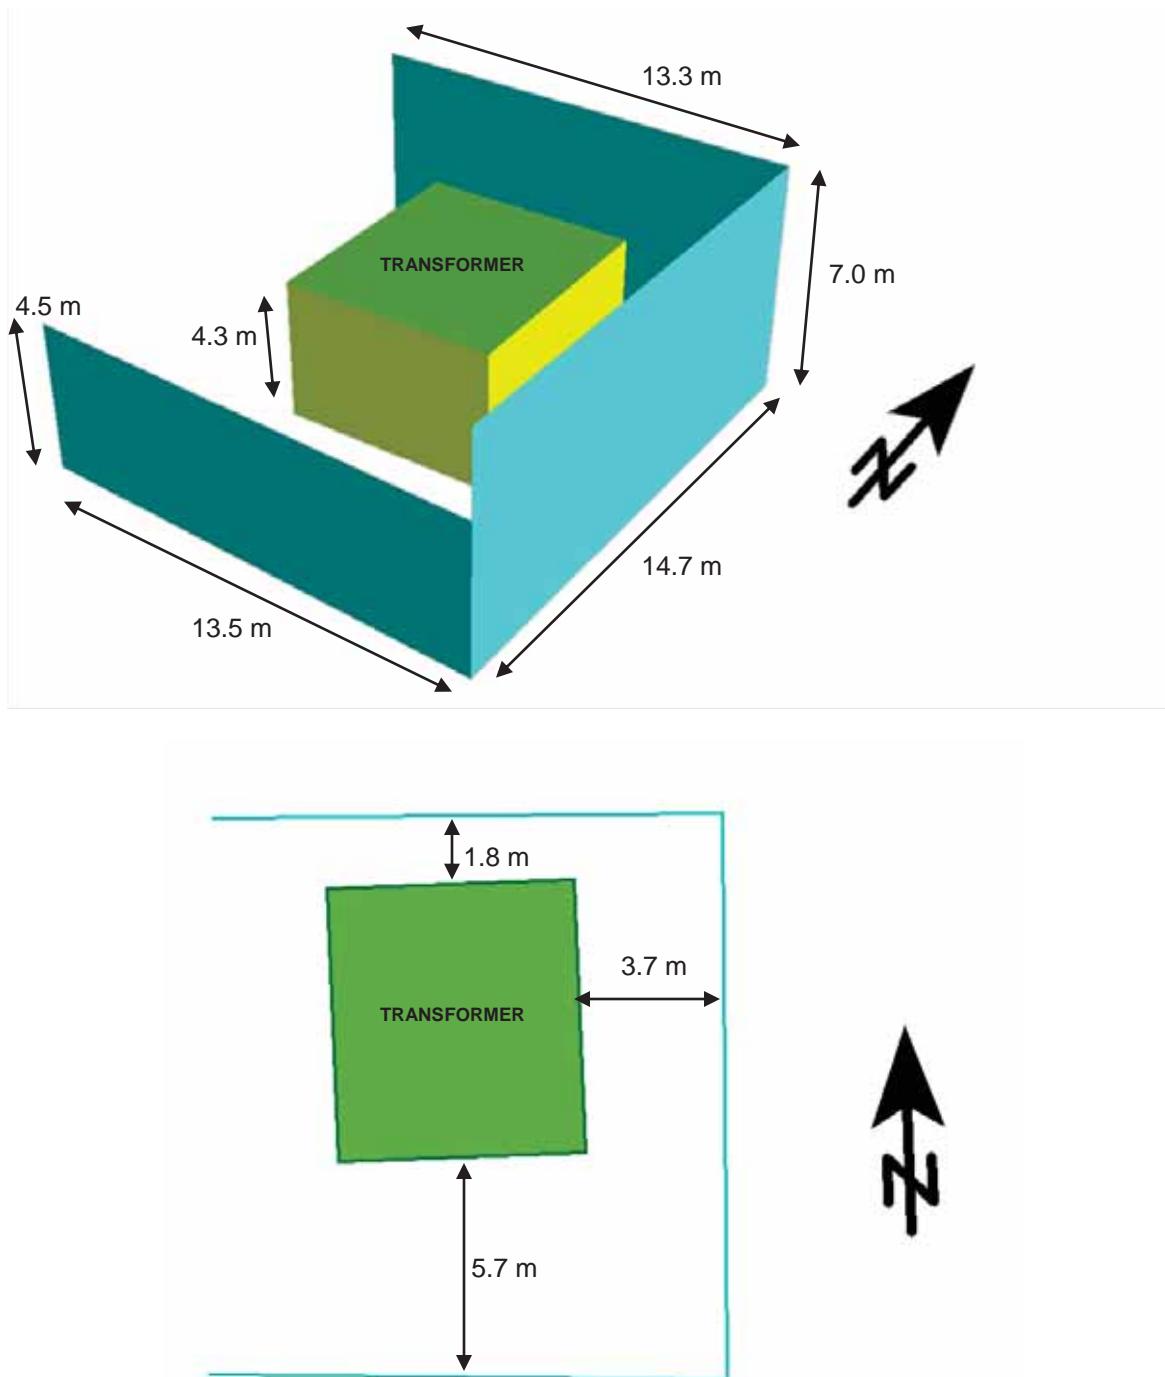

Figure 1 Dimensions and layout of noise barrier relative to transformer

5. Points of Reception

The Noise Impact Summary Table, provided in Section 9, lists all of the points of reception within 2000 metres of the Project turbines and the associated coordinates as per Section 6.1 d) of the MOE noise guideline (PIBS 4709e). The points of reception have been classified into four different categories which are outlined in Table 3. 3, below.

Table 3. Point of Reception Classifications

Class	Description	Quantity		Remarks
		Within 1.5 km	Within 2 km	
NP	Non-participating	1140	1720	MOE Limits Apply
PR	Participating	78	78	MOE Limits Do Not Apply
VNP	Vacant Lot Non-participating	382	529	MOE Limits Apply
VPR	Vacant Lot Participating	63	63	MOE Limits Do Not Apply

The classifications NP and VNP are both non-participating and are subject to the noise level limits outlined in the MOE noise guideline (PIBS 4709e, see Table 1).

The classifications PR and VPR are both participating and are not subject to the noise level limits outlined in the MOE noise guideline. Participating points of reception are associated with the wind farm development via a legal agreement with the owner of the subject property, to allow the installation and operation of wind turbines or related equipment.

6. Detailed Noise Impact Assessment

The noise impact analysis for the Project was completed using the Cadna/A environmental noise modelling software. The noise modelling was conducted in accordance with the international standard ISO 9613-2. The noise predictions were calculated using downwind propagation from each source to each point of reception. This method produces a theoretical worst case prediction at each point of reception. The noise impact calculations were completed using octave band spectral values in the range of 63 to 8000Hz for each integer 10 metre height wind speed from 6 to 10m/s.

The noise model was configured to calculate the resultant noise impact at each point of reception within 1500 metres of the Project turbines as per Sections 6.3 and 6.4.1 of the MOE noise guideline (PIBS 4709e). The contribution of each noise source located within 5000 metres from each point of reception was included in the noise impact calculation according to Section 6.4.9 of PIBS 4709e. The air attenuation and ground attenuation calculation within the model were configured according to Section 6.4.10 of PIBS 4709e.

The noise impact at each point of reception, for each integer 10 metre height wind speed from 6 to 10m/s, is presented in the Noise Impact Table (Section 9). All of the noise predictions were completed in accordance with the detailed requirements of the MOE noise guideline (PIBS 4709e).

6.1 Ground Absorption

An investigation by Evans and Cooper (2012)² on differences between predicted and measured wind turbine noise levels showed that for concave shaped terrain, using hard ground under ISO 9613-2 provides a more accurate prediction methodology than with ground absorption. In order to determine whether any receptors could be deemed to be on concave ground, the criterion presented in the UK Institute of Acoustics document *A Good Practice Guide to the Application of ETSU-R-97 for the Assessment and Rating of Wind Turbine Noise* was used.

Under the approach taken in this document, ground is defined as concave if a turbine-receptor pair fulfils the following criterion:

$$h_m \geq 1.5 \times \left(\frac{\text{abs}(h_s - h_r)}{2} \right)$$

Where h_m is the mean height above ground for noise transmission as defined in ISO 9613-2, and h_s and h_r are the local heights of the source and receiver above ground.

Analysis was conducted on all turbine-receptor pairs, and it was determined that 34 turbine-receptor pairs satisfy this criterion. While the terrain around the Jericho study area is relatively flat, for these 34 turbine-receptor pairs, noise levels were determined using a ground absorption coefficient of 0.0. The individual noise levels were then summed logarithmically to determine the overall noise levels at these locations. A table showing all 34 turbine-receptor pairs, partial turbine levels and overall turbine levels is attached in Appendix E.

6.2 Terrain screening

Wind turbines have been modelled as a single point source at hub height, consistent with standard modelling practice for wind turbines. However, as aerodynamic noise is generated from the blade surfaces, it is noted that noise will be produced over the swept area of the turbine. This means that terrain screening, or a ground barrier

² Comparison of Predicted and Measured Wind Farm Noise Levels and Implications for Assessments of New Wind Farms, Acoustics Australia 40(1), 28-36 (2012)

effect, would be reduced unless the entire swept area of the turbine blades is screened from a noise receptor. In order to account for this reduction in screening, modifications were made to the calculation algorithm for the calculation of wind turbine noise levels.

The screening attenuation (A_{bar}) is calculated under ISO 9613-2 using the following equation (equation 14 from the ISO standard):

$$A_{bar} = D_z - A_{gr} > 0$$

$$D_z = 10\log \left[C_1 + \frac{C_2}{\lambda} C_3 z K_{met} \right]$$

The values C_1 , C_2 and C_3 are calculation parameters that vary based on the conditions being assessed. The remaining values represent wavelength (λ), mean path difference (z) and a meteorological correction (K_{met})

For single diffraction, where ground reflections are not taken into account separately, values of $C_1 = 3$, $C_2 = 20$ and $C_3 = 1$ are used. In order to set ground screening to zero, values of $C_1 = 1$, $C_2 = 0$ and $C_3 = 0$ were used in the calculation algorithm for all calculated wind turbine noise levels.

As screening still applies to noise levels from the transformer, a separate calculation was carried out, using the default ISO 9613-2 values of $C_1 = 3$, $C_2 = 20$ and $C_3 = 1$ to calculate transformer noise levels. The transformer and turbine noise levels were then summed logarithmically at all receptors to obtain overall noise levels.

7. Results and Compliance

7.1 Cumulative Noise Levels

The results of the noise modelling in the Noise Impact Table (Section 9) show that the Project is predicted to operate in compliance with the MOE noise level limits at all points of reception within 1500 metres of the Project turbines. Appendix D includes noise contour maps for each integer 10 metre height wind speed from 6 to 10m/s and a sample calculation is provided in Appendix E.

The results presented in Section 9, Appendix D and Appendix E include the effect of a noise barrier as outlined in Section 4.2 on the north, east and south sides of the Project transformer substation. With the noise mitigation described above implemented, the Project is predicted to comply with the MOE sound level limits for Wind Turbines in Class 3 areas for all of the non-participating (NP) and vacant lot non-participating (VNP) points of reception assessed.

The closest non-participating receptors to the Jericho Wind Energy Centre are receptors JER2573, JER2595 and JER5564. These receptors are all located at a distance of 550 metres from the nearest Jericho wind turbine generator, and have predicted noise levels for all wind speeds of 38.9, 39.5 and 39.1 dB(A) respectively.

The non-participating noise receptors with the highest predicted noise level are receptors JER3210, JER5293, JER5563 which all have predicted noise levels of 39.9 dB(A) at a 6 m/s 10 metre height wind speed.

7.2 Transformer Noise Levels

The closest sensitive noise receptors to the transformer substation are JER2532, JER5563 and JER2573. Turbine noise levels at these receptors are presented in the table below.

Table 4. Predicted wind turbine noise levels at the closest sensitive receptors to the Jericho Wind Energy Centre substation

Receptor	Predicted wind turbine noise level at varying 10 metre height wind speeds (dB(A))				
	6m/s	7m/s	8m/s	9m/s	10m/s
JER2532	38.7	38.7	38.7	38.7	38.7
JER2573	38.3	38.3	38.3	38.3	38.3
JER5563	39.3	39.3	39.3	39.3	39.3

The transformer was modelled using two different methods. In the preferred modelling method, the transformer was modelled as a three-dimensional structure using the geometry obtained from engineering drawings of the transformer. The results presented in Section 9 were prepared using the preferred modelling methodology.

In the alternative modelling method, the transformer was modelled as a single point source located at cover height of the transformer (4.27 metres). Using these two modelling methodologies and the noise barrier presented in Section 4.2, transformer noise levels were predicted at the nearest sensitive receptors. These two methodologies were used to demonstrate compliance with the most conservative assumptions, as requested by the Ministry of the Environment.

The following table summarises modelled transformer noise levels for the preferred and alternative modelling methodologies.

Table 5. Predicted transformer noise levels using preferred and alternative methodology

Receptor ID	Predicted Transformer Noise Level	
	Preferred Methodology	Alternative Methodology
JER2532	32.6	33.0
JER2573	29.9	30.4
JER5563	30.8	31.1

Using the modelled values shown above, the cumulative transformer and turbine levels based on a logarithmic sum of the contributing noise levels for both source types is shown in the following table.

Table 6. Cumulative transformer and turbine predicted noise levels

Receptor	Predicted cumulative transformer and turbine noise level at varying 10 metre height wind speeds (dB(A))									
	6m/s		7m/s		8m/s		9m/s		10m/s	
	Pref.	Alt.	Pref.	Alt.	Pref.	Alt.	Pref.	Alt.	Pref.	Alt.
JER2532	39.7	39.7	39.7	39.7	39.7	39.7	39.7	39.7	39.7	39.7
JER2573	38.9	39.0	38.9	39.0	38.9	39.0	38.9	39.0	38.9	39.0
JER5563	39.9	39.9	39.9	39.9	39.9	39.9	39.9	39.9	39.9	39.9

As can be seen, for all wind speeds, and for both modelling methodologies, the proposed transformer and barrier configuration results in compliance with noise criteria under the MOE document *Noise Guidelines for Wind Farms*. The transformer noise levels include a 5 dB(A) adjustment for tonality, in accordance with NPC-104.

9. Summary Tables

Table 7. Wind Turbine Acoustic Emission Summary Tables

Tables are provided with A-weighted octave band sound power levels in order to be consistent with manufacturer supplied data. Manufacturer supplied data provide all octave band sound power levels in A-weighted levels. The below tables are replicated in Appendix F as linear (unweighted) octave band levels. Please note that the levels shown in Appendix F are equivalent to the levels presented in the following tables.

Notes:

(1) - The individual levels provided in this table are taken from the relevant noise impact assessment reports, being the *Suncor Adelaide Wind Power Project Noise Assessment Report* by HGC Engineering dated July 2013 and the *Cedar Point Wind Power Project Noise Assessment Report* by HGC Engineering, dated June 2013.

(2) - Between the date of first concordance and later revisions, the *Suncor Adelaide Wind Power Project Noise Assessment Report* was updated to include a much greater number of receptors, and receptor IDs were changed. For consistency, the original receptor numbers are used in this table. However, there is only one receptor that is within 1500 metres of both Suncor Adelaide and NextEra Jericho wind turbine generators: JER4710. This receptor was originally identified as R042 in the earliest revision of the Suncor Adelaide Noise Report, but in later revisions was changed to be receptor 43. For clarity, the new value is provided in parentheses in this table.

(3) - The total presented in this column is not the logarithmic sum of the individual levels from each report, but the total obtained by noise modelling of all noise sources associated with the three projects, and other planned or existing projects within 5km as per the Ontario Ministry of the Environment *Noise Guidelines for Wind Farms*.

(4) - Suncor Adelaide receptor R007 is located on the same parcel as Suncor Adelaide receptor R013. This parcel is a Vacant Lot Participating Receptor in the Jericho Wind Energy Centre assessment, receptor JER4530

(5) - Suncor Cedar Point receptor 235 is located on the same parcel as Suncor Cedar Point receptor 2611. Ground-truthing identified that Suncor receptor 235 was placed on a garage/barn structure, with 2611 placed on the associated residence. This parcel has Non Participating Receptor JER5160 in the Jericho Wind Energy Centre assessment.

(6) - Suncor Cedar Point receptor 1141 is located on the same parcel as Suncor Cedar Point receptor 2462, and they are within 3 metres of each other. This parcel has Non Participating Receptor JER5042 in the Jericho Wind Energy Centre assessment.

Noise Impact Summary Table**Notes to Table:**

1. As per section 6.1 a), of PIBS 4709e, points of reception up to 2000 metres are identified in the table and the project site plan. However, as per sections 6.3 and 6.4.1 noise levels have only been predicted for points of reception within 1500 metres of a Project wind turbine. Therefore the noise level results for points of reception at distances of greater than 1500 metres from the nearest Project wind turbine appear as dashes (-). The associated limits and compliance columns also appear as dashes (-) for these entries as compliance assessment is not required by the guideline.
2. Participating receptors are not subject to the MOE noise limits and in these cases the noise limit entries are represented as dashes (-), in such cases the associated compliance column also appears as a dash (-) since a compliance assessment is not required.

Table Abbreviations:

NP	-	Non-participating Point of Reception
VNP	-	Non-participating Vacant Lot Point of Reception
PR	-	Participating Point of Reception
VPR	-	Participating Vacant Lot Point of Reception
C	-	Compliant with MOE sound level limits for Wind Turbines in Class 3 areas (See Table 1)
NC	-	Not Compliant with MOE sound level limits for Wind Turbines in Class 3 areas (See Table 1)

1 INTRODUCTION

NextEra Energy Canada, ULC is proposing to develop the Parkhill Interconnect Project (“Project”), which is subject to Ontario Regulation 359/09 (Renewable Energy Approvals (REA) under Part V.0.1 of the Ontario Environmental Protection Act (EPA)) [1]. NextEra Energy Canada, ULC is seeking a Renewable Energy Approval from the Ontario Ministry of the Environment (MOE).

The Parkhill Interconnect Project will consist of a substation and a switching station. The substation will consist of two main power transformers. The substation at the Point of Interconnect (POI) will be owned within a Co-Owners Agreement (Tenants-in-Common Agreement) among Bornish Wind LP, Kerwood Wind, Inc. and Jericho Wind Inc. These three companies are wholly-owned subsidiaries of NextEra Energy Canada, ULC. The parent company of NextEra Energy Canada, ULC is NextEra Energy Resources, LLC, with a current portfolio of nearly 8,500 operating wind turbines across North America.

At the request of NextEra Energy Canada, ULC (the “Client” or “NextEra”), GL Garrad Hassan Canada, Inc. (GL GH), prepared a Noise Impact Assessment (NIA) as per the requirements of the REA, Technical Guide to Renewable Energy Approvals and in accordance with Appendix A of the Ministry of the Environment’s publication entitled, “Basic Comprehensive Certificates of Approval (Air) – User Guide”, as amended periodically and available from the Ministry [2].

The purpose of this study is to verify compliance of the Project to current Ontario noise guidelines by calculating the noise levels generated by the Project at all Points of Reception in the vicinity of the main power transformers.

This study comprises 3 main sections: (i) a general description of the project area, noise sources and noise receptors, (ii) a description of the Project’s components including noise sources and acoustic barriers, and (iii) noise impact assessment results.

2 GENERAL DESCRIPTION OF PROJECT AREA

2.1 General Characteristics

The proposed Parkhill Interconnect Project is located in south-western Ontario, in the Municipality of North Middlesex, Middlesex County, Ontario. More specifically, the Project is located south of New Ontario Road, east of Evergreen Road, north of naira Road and west of Cassidy Road. It has a total project area of approximately 43.7 ha. Project components will be installed on a privately-owned agricultural lot.

The Project consists of a switching station and a substation. The substation includes two (2) 135/225 MVA -121/525 kV LTC transformers with ONAN/ONAF/ONAF cooling rating. The switching station and substation have been strategically sited on lands that the Client holds under lease options.

The landscape in the study area is predominantly characterized by agricultural fields and associated farms punctuated with numerous hedgerows, isolated woodlands, and the occasional watercourse. Photographs included in Figure 2-1 show typical views of the land and features of the study area.

Figure 2-1: Land Features of the Parkhill Interconnect Site

2.2 Land Use Description

The site is located within two two-tiered municipal systems. The County of Middlesex makes up the upper tier of the region, while Adelaide Metcalfe, North Middlesex and Strathroy-Caradoc, along with five additional townships and municipalities, have lower tier municipal status. Agriculture is the predominant economic activity and land use throughout the County of Middlesex; however, the municipalities that comprise the study area each have features creating distinct community character. Surrounding properties and lands are characterized as low density residential while also including a number of agricultural buildings. Other land use within the study area includes rural and urban-rural, providing a foundation for manufacturing, business and tourism development. Access to the Project is provided by small paved and unpaved municipal roads that stem from larger municipal roads. The municipal zoning map is shown in Appendix A.

2.3 Baseline Ambient Noise Conditions

The MOE categorizes Points of Reception into three classes: 1, 2, and 3. Class 1 refers to an acoustic environment typical of a major population centre where the background noise is dominated by the urban hum. These areas are highly urbanized and have moderate to high noise levels throughout the day and night. Class 2 areas have an acoustic environment characterized by low ambient sound levels between 19:00 and 07:00, whereby the evening and night-time levels are defined by natural sounds, infrequent human activity and no clearly audible sounds from stationary sources (e.g. industrial and commercial facilities). Class 3 areas are typical of rural and/or small communities (i.e. with populations of less than 1000) and an acoustic environment that is dominated by natural sounds with little or no road traffic.

Within the study area, the main sources of ambient sound that currently exist include:

- Vehicular traffic noise from nearby roads;
- Vehicular traffic on the local concession and side roads, some of which are gravel roads;
- Occasional sounds stemming from agricultural activities;
- Occasional sounds due to anthropogenic domestic activities; and
- Natural sounds.

Based on these conditions, all Points of Reception are considered as having a Class 3 acoustical environment, which requires that the permissible sound level not exceed the following values at the PoR:

Table 2-1: Permissible sound levels for a Class 3 area

Time of Day	One Hour L_{eq} [dBA]
07:00 – 19:00	45
19:00 – 23:00	40
23:00 – 07:00	40

2.4 Points of Reception

The “Basic Comprehensive Certificates of Approval (Air) – User Guide” [2] requires a search radius of up to 1,000 m for Points of Reception (POR). This study includes Points of Reception found within 1,500 m of the proposed main power transformer locations. A total of 19 buildings were identified and provided by the Client [3], whereas 9 of the buildings within 1,500 m of the transformers were considered Points of Reception for this NIA. GL GH did not validate the Points of Reception on-site.

13 vacant lots with a zoning designation that considers houses as a permitted use were also found by GL GH within 1,500m of the main power transformer location, by using available Ontario base mapping, satellite imagery and parcel fabric data. In accordance with the REA requirements, “vacant lot receptors” (VLR) were placed on these vacant lots, in a location consistent with the building pattern of the area, which is typically alongside the road frontage. For the sake of consistency and given the unknown location of any future houses on these lots, VLRs were placed half-way on the front yard lot line abutting the road.

Table 2-2 below provides all PoR locations that were analyzed in this study.

Table 2-2: List of identified Points of Reception

3 PROJECT DESCRIPTION

The Parkhill Interconnect substation will “step-up” the electricity conveyed via a 115 kV transmission to 500 kV and will connect via a switching station to an existing Hydro One 500 kV line that runs adjacent to the Project location. The substation equipment will include an isolation switch, a circuit breaker, a step-up transformer, transmission switch gear, instrument transformers, grounding and metering equipment. All substation and switching station grounding equipment will meet the Ontario Electrical Safety Code.

It is important to note that the 115 kV line running to the project and connecting to Hydro One’s existing 500 kV line is common to three of NextEra’s Projects, i.e. Adelaide, Bornish and Jericho Wind Energy Centre.

Based on the classification system outlined in Part II of O. Reg. 359/09, the Parkhill Interconnect Project is located in a Class 3 rural area.

Wind turbines belonging to three different projects (Adelaide, Bornish, and Jericho) will convert wind into Alternating Current (AC) electricity. The local transformers of each project will raise the voltage to 115 kV. The combined power of the three projects will then be directed to the Parkhill Interconnect substation that will elevate the voltage to 500 kV. The Project will be made up of the following key facilities, equipment and technologies:

- Collector system and two (2) 3-phase 225 MVA transformers at the substation; and
- Access roads and maintenance building.

A scaled location map, indicating the topography, nature of the neighborhood surrounding the facility, location of adjacent buildings, structures and receptors has been attached as Appendix B.

3.1 Life of the Project

The expected life of the Project will be a minimum of 20 years (the length of the power purchase agreement), but may continue to operate or be repowered once the power purchase agreement expires. At the end of the Project life the Project will be decommissioned in accordance with the Decommissioning Plan Report.

3.2 Operating Hours

The main transformers in the Parkhill Interconnect substation will be operating continuously throughout the day and are assumed to emit the same amount of noise during the daytime as during night time. Therefore, no changes will be made to the sound power level of the main transformers when running the model to account for time of day. The sound pressure level that will be compared to the permissible noise levels in Table 2-1 will be the same for daytime operation and night time operation.

3.3 Noise Sources

3.3.1 Approach to the Study

The sound pressure level at each Point of Reception for the Parkhill Interconnect Project was calculated based on the ISO 9613-2 method [4]. This is a widely used and generally accepted standard for the evaluation of noise impact in environmental assessments. The desired sound pressure level of the proposed main power transformers was obtained from the Client and can be found in Appendix C, while the transformer sound power level (PWL) was estimated on the basis of the technical specifications and dimensions. The software package CadnaA, which implements ISO-9613-2, was used to predict the sound pressure levels at the PoRs.

3.3.2 Noise Sources Summary

The primary noise sources of the current Project design are the main power transformers located in the central portion of the Project area.

The cumulative noise impact from the nearby proposed wind farm project, Bornish Wind Energy Centre, has not been included in the analysis since the closest proposed with turbine for this project is >5 km away.

No other equipment at the substation and at the switching station has been included in the present NIA. Any ancillary equipment installed is considered to have a significantly lower acoustical level compared to the main power transformers.

3.3.3 Main Transformers

This Project uses one (2) main step-up transformers located at the Project's substation. The electrical and physical specifications for the substation's transformers were provided by the Client [5] and are shown in Appendix C. Details are presented in Table 3-1 below. This study assumes that the 225-MVA / 525 kV main transformers at the substation are fluid-immersed devices with forced air cooling (rated ONAN/ONAF/ONAF).

The transformer walls were modeled as vertical area sources and the transformer top was modeled as a horizontal area source. GL GH considers that given the relatively large size of the transformers and barriers, modeling the transformers as an area source is a more realistic approach than assuming a point source, in this case. Not only does the transformer not behave like a point source, but it also yields a less conservative sound pressure level at the nearest PoR. Refer to Section 4.2 for a comparison of results at most impacted dwelling.

The base of each transformer has been raised to 1 m above ground level, as requested by the Client. The vertical area sources used to represent the transformer walls were given a height of 4.5 m and placed 1 m above ground.

The Client is currently in talks with the manufacturer to ensure that the broadband Sound Pressure Level (SPL) value of the transformer will not exceed 75 dBA when measured according to IEEE Std C57.12.90-2006 [7]. The proposed audible sound level of 75 dB was then converted to a PWL value of 100.8 dBA

using IEEE Std C57.12.90-2006. A 5 dBA penalty for tonality, as per Publication NPC-104 (Sound Level Adjustments) was applied for a resulting PWL of 105.8 dBA. A typical transformer octave band sound distribution for a large transformer from the Handbook of Acoustics [8] was used and fitted to match the broadband value of 105.8 dBA.

Details on each noise source are presented in Table 3-1 below.

Coordinates of the transformers and a table with the derived octave band spectra are listed in Appendix C.

3.3.4 Sound Barrier

In order to achieve compliance with the current noise propagation model, both transformers will require a noise barrier. The type of barrier used in this noise study is one that can be described as of absorptive type with an Absorptive Coefficient of 0.85. The acoustic barriers should have a surface density of at least 20 kg/m² and have a closed surface free of gaps and cracks, such as Armtec's Durisol. A 5.5 m tall barrier (equal to the height of the transformer raised by 1 m) was modeled on the south side of each transformer, approximately 6 m away from the southern edge of the transformer. The barriers are illustrated on the noise map in Appendix D. The coordinates of the barrier can be found in Table 3-2.

3.3.5 Summary Tables

Table 3-1: Noise Source Summary Table

Source ID	Source Description	Sound Power Level [dBA] ¹	Source Location	Sound Characteristics	Noise Control Measures
T1	Main Transformer	105.8	O	S-T	B
T2	Main Transformer	105.8	O	S-T	B

1. 5 dBA tonal penalty included

Source location: (O): Outside building

Sound Characteristics: (S): Steady; (T): Tonal

Noise Control: (B): Barrier

Table 3-2: Coordinates of Barrier Edges. UTM 17 NAD83

ID	Description	Easting	Northing
B1a	Barrier 1, point a	452720	4774653
B1b	Barrier 1, point b	452747	4774646
B2a	Barrier 2, point a	452761	4774643
B2b	Barrier 2, point b	452788	4774637

4 NOISE IMPACT ASSESSMENT

As stated in MOE's publication NPC 232, the sound level limit at a point of reception must be established based on the principle of "predictable worst case" noise impact.

The sound pressure level at each Point of Reception for the aggregate of all noise sources associated with the Parkhill Interconnect Project was calculated based on the ISO 9613-2 method.

The ISO 9613 standard [6] provides a prediction of the equivalent continuous A-weighted sound pressure levels at a distance from one or more point sources under meteorological conditions favorable to propagation of sound emissions.

The method consists of octave-band algorithms (i.e. with nominal mid-band frequencies from 63 Hz to 8 kHz) for calculating the attenuation of the emitted sound. The algorithm takes into account the following physical effects:

- Geometrical divergence – attenuation due to spherical spreading from the sound source;
- Atmospheric absorption – attenuation due to absorption by the atmosphere; and
- Ground effect – attenuation due to the acoustic properties of the ground.

ISO-9613-2 parameters were set as follows:

- Ambient air temperature: 10°C;
- Ambient barometric pressure: 101.32 kPa;
- Humidity: 70%;
- Ground factor: A detailed map of Hard Ground (0) and Porous Ground (1.0) was used to model the ground attenuation.;
- Transformer height and dimensions: see Appendix C;
- PoR height: 1.5m and 4.5 m; and
- The effect of topography was considered.

A discussion of the Ground Factor methodology can be found in section 4.1.

Additional calculations concerning attenuation from foliage were not performed in this report, implying that the values calculated for sound attenuation are likely to be conservative in areas where there is foliage present in the line of sight between any noise source and a Point of Reception. The estimated accuracy of the ISO 9613 method, as stated in ISO 9613-2, is ± 3 dB.

First order acoustic reflections were not included in the study since it is assumed that the sound reflection coefficient is lower than 0.2 [6].

The transformer noise emission ratings used for each octave band are specified in Appendix C. The noise impact was calculated for each Point of Reception located within 1,500 m of a source of sound from the Project, and the calculated noise level was then compared with the applicable permissible sound level for each receptor, as presented in Table 4-2.

4.1 Ground Factor Methodology

GL GH has previously assumed a global ground factor of 0.7 to model the ground factor attenuation. However, as per recent requirements, GL GH has undertaken a refined estimate of the ground factor attenuation around the project interconnection substation. This section presents a detailed ground factor calculation for the area expected to be most sensitive to ground factor assumptions. For the transformers-to-PoR 1 case, ground factors for the source, middle, and receiver regions have been calculated based on ISO 9613-2. The distance from the transformer to Receptor ID 1 is 610 m. Figure 4-1 below shows the regions and ground cover, including the gravel area around the substation.

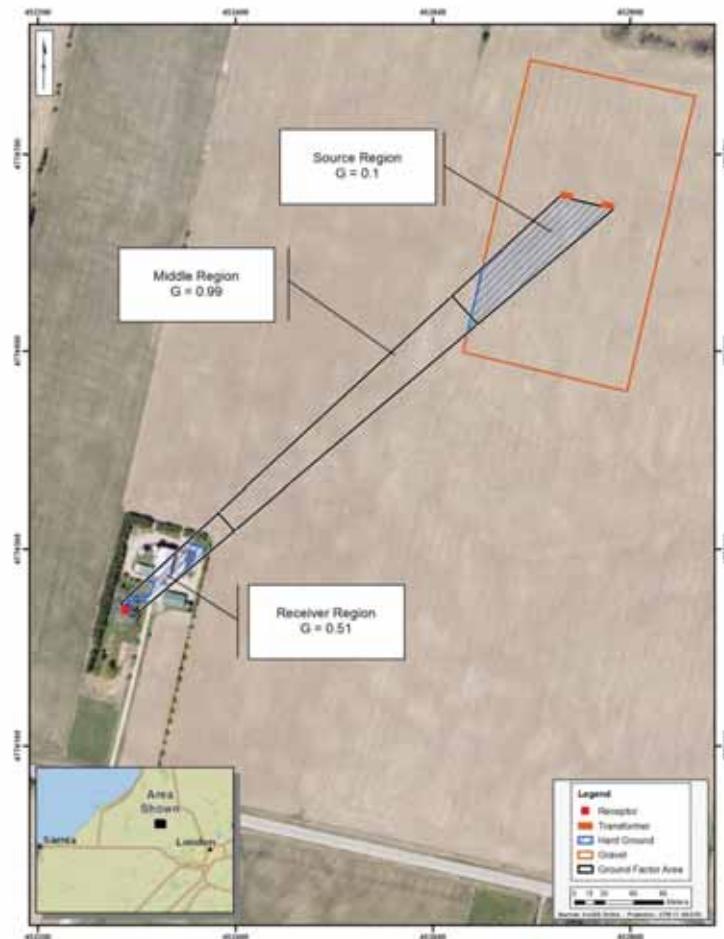

Figure 4-1: Ground factor coverage near Parkhill substation

Source region ground factor G_S

As defined by ISO 9613-2, the source region extends over a distance of $30h_S$ from the source towards the receiver, where h_S is the source uppermost height of 4.5 m. The source region length is therefore 135 m. NextEra has supplied site plans indicating that the area that will be covered with gravel. A geometric analysis has indicated that 90% of the source region is covered with gravel. Based on aerial photography, the remaining area is covered with porous ground. The source region ground factor G_S is then **0.1**, as per ISO 9613-2.

Receiver region ground factor G_R

As defined by ISO 9613-2, the receiver region extends over a distance of $30h_R$ from the receiver towards the source, where h_R is the receiver height of 4.5 m. The receiver region length is 135 m. Based on aerial photography, 49% of the receiver region is covered by hard ground. The receiver region ground factor G_R is then **0.51**, as per ISO 9613-2.

Middle region ground factor G_M

As defined by ISO 9613-2, the middle region stretches over the distance between the source and receiver regions. Based on aerial photography, 0.6% of the receiver region is covered by hard ground. The middle region ground factor G_M is then **0.99**, as per ISO 9613-2.

CadnaA Calculations

Two sets of CadnaA calculations have been carried out. The first uses the three ground factors calculated as described above:

$$G_S = 0.1$$

$$G_M = 0.99$$

$$G_R = 0.51$$

The second CadnaA calculation uses a global ground factor of 0.7 for all three regions.

When using the three ground factors, the estimated sound pressure level at PoR1 is below the 40 dBA limit, but higher when compared to using a global factor of 0.7.

Given this result, for this specific project, a different a more detailed approach for considering ground factor is thus implemented and explained below.

4.1.1 Site-specific ground factor approach

Geospatial imagery was used to produce a detailed shape file identifying hard ground. The shape file covers an area of at least 1.5 km around the substations transformers. All areas identified as having hard ground have been assigned a ground absorption of 0. All other areas, which are covered by farming area, brush, grass, etc. have been considered as porous ground and assigned a ground absorption value of 1.0, as detailed in ISO 9613-2.

Figure 4-2 below shows the regions and ground cover.

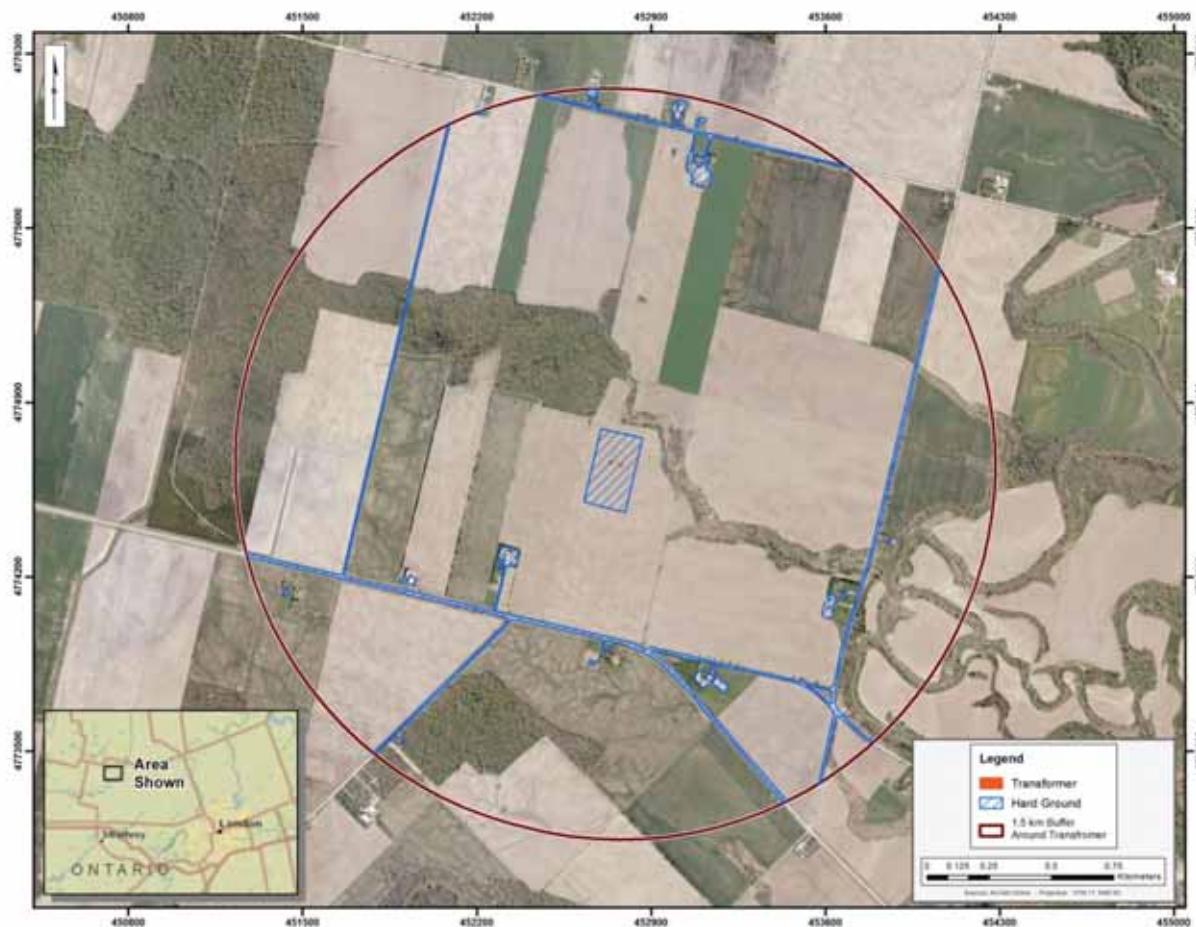

Figure 4-2 : Ground factor coverage for the entire Parkhill substation area

The worst case result at the most impacted receptor, PoR 1, is 38.8 dBA. This level is higher than results utilizing a global ground factor of 0.7, or three regional ground factors. The detailed site-specific methodology is therefore the most conservative of the three approaches for the most impacted receptor, and has been utilized in this assessment. The results are shown in Table 4-1 below.

Table 4-1: Comparison of three ground factor cases

Case	Case 1, Global G = 0.7	Case 2, Three G values	Case 3 Detailed map of hard ground and porous ground for entire project
Sound Pressure Level at PoR1 [dBA]	37.5	38.4	38.8

4.2 Results

Table 4-2 presents the sound pressure level at each point of reception within 1,500 m of the Main Power Transformers, and all are found to be compliant with daytime and night-time permissible sound levels per the MOE guidelines. The simulated noise iso-contour map is presented in Appendix D.

The shortest distance between a Main Power Transformers and a house is approximately 610 m (PoR 1 and T1). This distance was calculated starting from the center of a transformer. The shortest distance between a noise source at the Project and a vacant lot receptor is approximately 760 m (PoR 23 and T2).

Table 4-2: Acoustic assessment summary

Point of Reception ID	Description	Sound Level at PoR Level Lr [dBA]	Verified by Acoustic Audit	Performance Limit, Night/Day [dBA]	Compliance with Performance Limit

As discussed in section 3.3.3, GL GH has modeled the transformers as area sources. For comparison, if the transformers are modeled as point sources, at a conservative height of 4.75 m, with all other parameters kept constant, PoR 1 yields a sound pressure level of 37.6 dBA, whereas the area source approach yields a sound pressure level of 38.8 dBA, as illustrated in Table 4-2.

4.3 Mitigation Measures

The overall predicted noise levels for all identified Points of Reception, based on site operations, comply with performance limits for daytime and night-time operations. As a result, no mitigation is deemed required to ensure compliance with MOE guidelines.

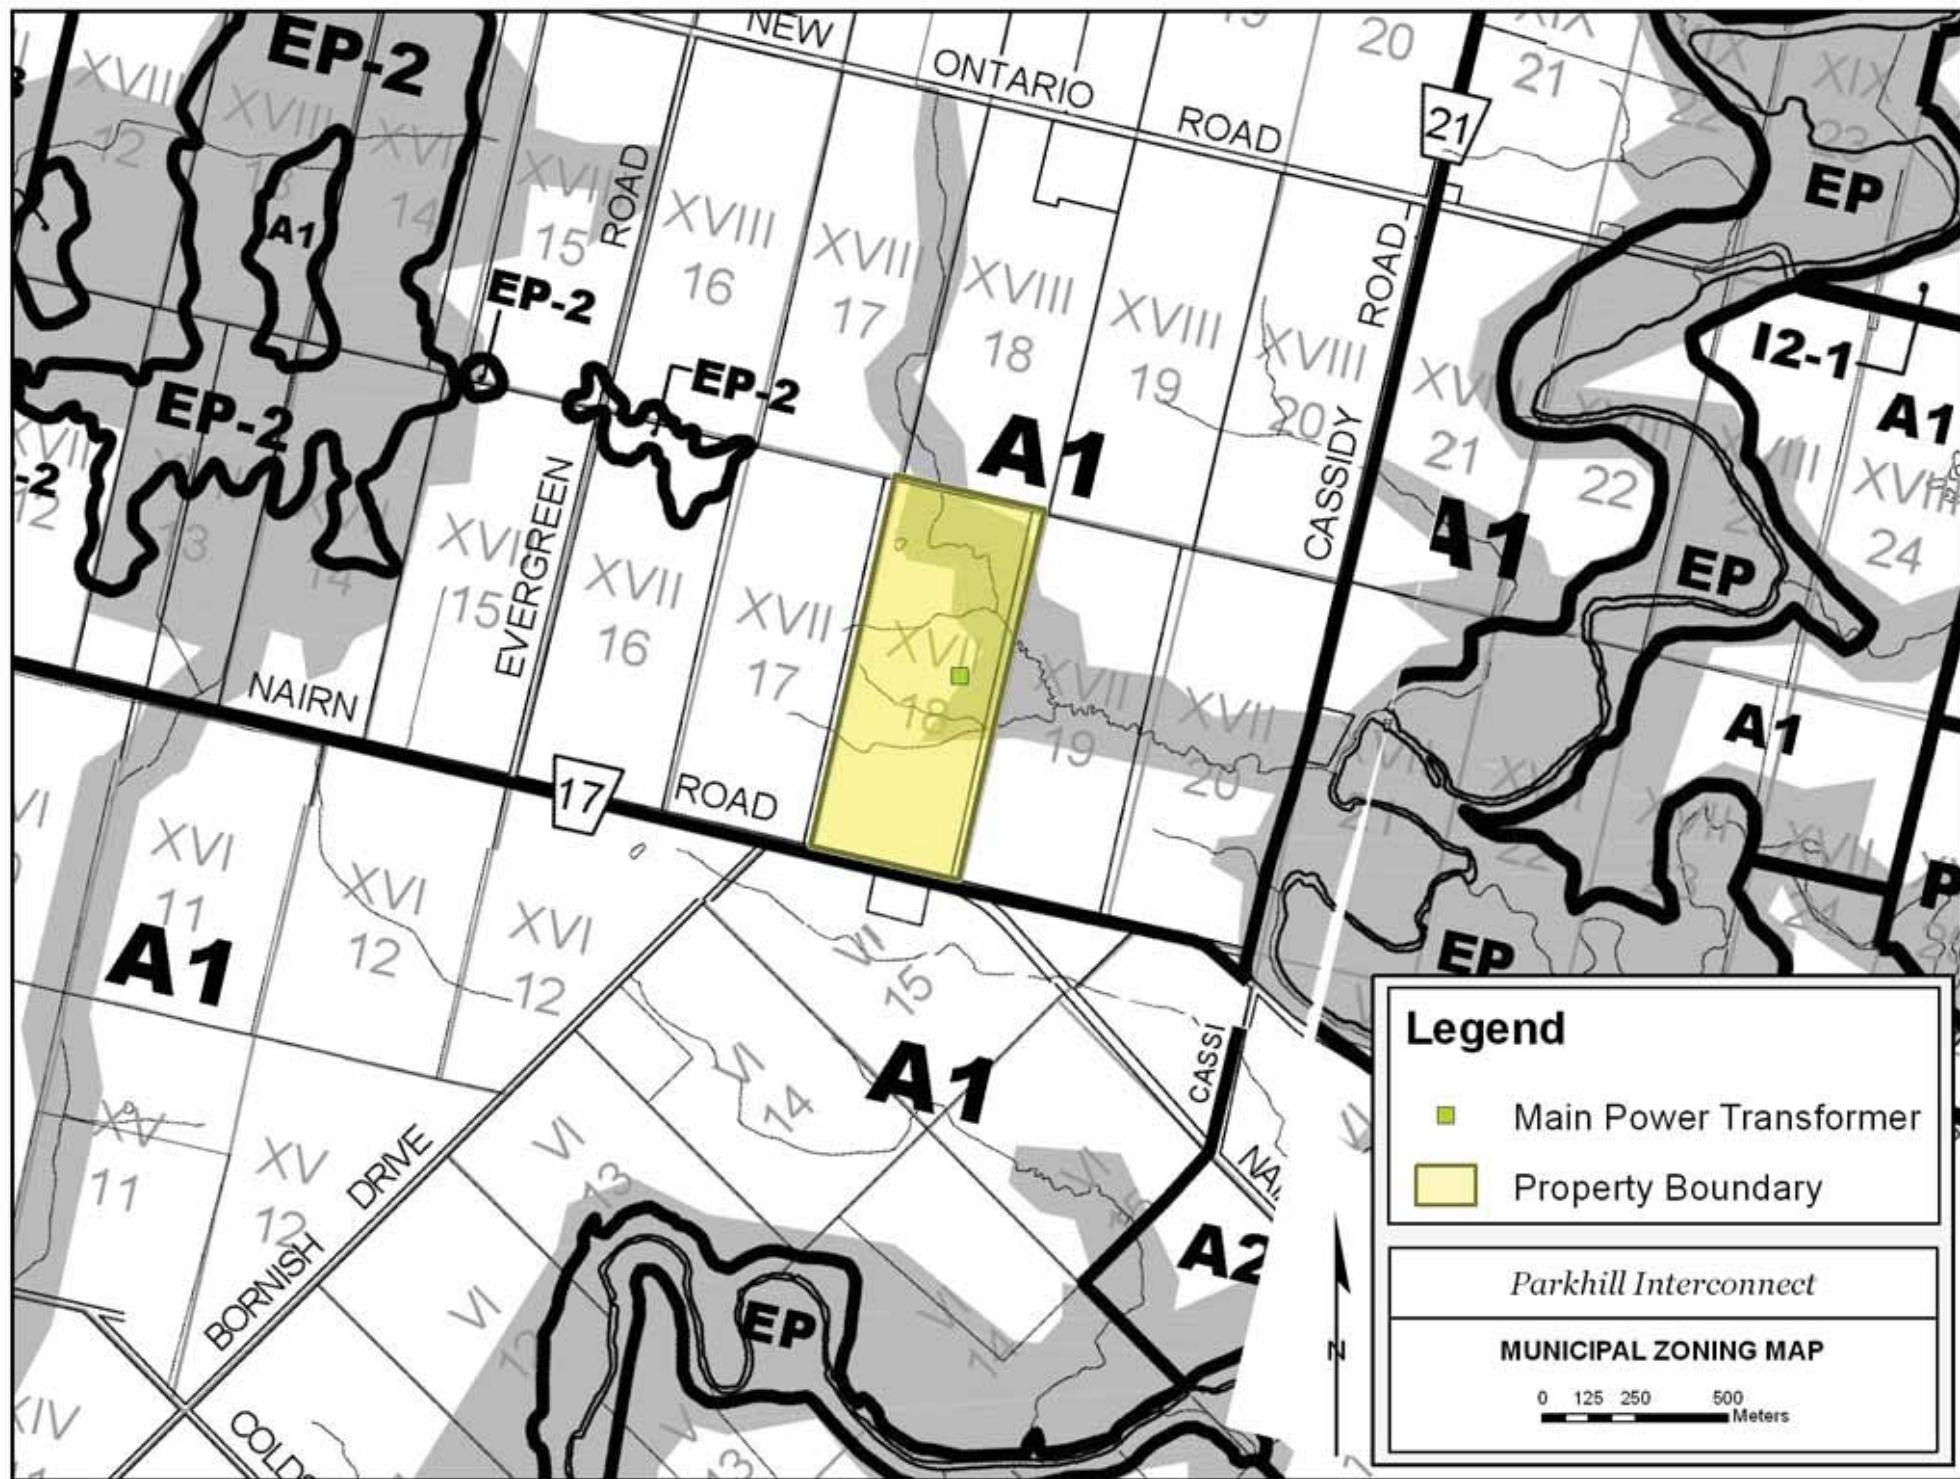

5 CONCLUSION

GL GH calculated the predicted noise levels generated by the Parkhill Interconnect Project based on the ISO 9613-2 model using CadnaA software. Based on the approach presented in this study and a set of assumptions related to noise sources of the Project and noise receptors, the Project is considered to be compliant with the daytime and night-time MOE permissible sound limits for Class 3 areas.

APPENDIX B PROPOSED LOCATION AND TOPOGRAPHIC MAP

APPENDIX C NOISE SOURCES

Noise Sources

Source ID	Description	Sound Power Level1 [dBA]	Coordinates (NAD83-UTM17)	
			X	Y
T1	Main Transformer	105.8	452735	4774658
T2	Main Transformer	105.8	452777	4774648

Includes 5dBA Tonal Penalty

Specifications of Noise Sources

225 MVA Main Power Transformer

Maximum Audible Sound Level: 75 dBA,
as per manufacturer documentation
Total Perimeter: 49.1 m
(12.3 m wide by 5.95 m deep, including 2 m offset from three fan-cooled surfaces)
Effective Height: 4.75 m without cooling tank
Top Area: 145.3 m²
Estimated Total Surface Area (S): 378.5 m²
Estimated Sound Power Level (without penalty): 100.8 dBA as per [7]

225 MVA substation main transformer octave band spectrum (including 5 dB penalty)¹
